First and foremost, I would like to express my sincere gratitude to my supervisor Dr. Jeffrey K. Atkinson, whose encouragement, guidance and support enable me to finish this thesis. Besides my advisor, I would like to thank the rest of my committee members Dr. Hongbin (Tony) Yan, Dr. Heather Gordon and my previous committee member Dr. Martin Lemaire for their encouragement, helpful advice and insightful comments. My thanks also go to Tim Jones and Razvan Simionescu for their help in Mass and NMR Spectroscopy. I would like to thank to the Centre for Medical Countermeasures against Radiation (CMCR) at the University of Pittsburgh for their financial support through Pilot Project awards to Dr. Atkinson, and for performing all of the biological testing.

I would like to thank all the present and past group members from our group. I enjoyed while working at the lab with Mikel Ghelfi, Parthajit Mukherjee, Ravi Shaker and Joshi. Finally I would like to show my gratitude to my parents and family members for their encouragement and constant support.
Abstract

Ionizing radiation is known to initiate apoptosis in mammalian cells by causing the transformation of cytochrome c into a peroxidase, which results in the specific peroxidation of the mitochondrial phospholipid cardiolipin. Here we report the design and synthesis of 8 imidazole fatty acid derivatives that bind to the cyt c:CL complex and inhibit the peroxidase activity required for the initiation of apoptosis. We postulate that imidazole acts as a sixth ligand to the haem iron and stops the interaction with H$_2$O$_2$. Two mitochondrially directed analogues (3-hydroxypropyl)triphenylphosphonium esters) of 12-imidazole-stearic acid and 12-imidazole-oleic acid not only were demonstrated to be peroxidase inhibitors in vitro, but were also extraordinarily effective in protecting mice from lethal doses (9 Gy) of ionization radiation. We studied the structure activity relationship to a group of triphenyl phosphonium derivatives containing imidazole at different positions on the fatty acid chain, and observed that the C$_8$-imidazole stearate analogue had marginally better activity than the others. But overall, the structure activity result were remarkable “flat” with all compounds prepared having rather similar inhibitory strength. We also synthesized carnitine mono and di-esters of 12-imidazole fatty acids but full biological data is not yet available for these compounds.

1. Introduction

The March 11th, 2011 earthquake and tsunami in Japan caused extensive damage to the Fukushima Daiichi nuclear power generating station. This disaster brought to the public’s attention the very serious concerns of human exposure to ionizing radiation. However, humans are exposed to radiation in other ways: airplane flight crews are exposed to cosmic radiation during high altitude flights, and patients receiving radiation therapy for solid tumours can be received very high doses of focused radiation on particular tissues. Ionizing radiation induces controlled, or programmed, cell death process called apoptosis.¹ This is thought to be initiated by the generation of reactive oxygen species (ROS).² Unfortunately, during the irradiation of tumour cells, normal cells are also affected, leading to the loss of non-diseased tissue. Cancer patients have been treated with electromagnetic radiation (photons), such as X-rays and gamma rays, and particulate radiation, usually electrons and, to a lesser extent, neutrons and protons.³ There are no effective solutions to protect non-cancerous cells from the damaging effects of ionizing radiation.

It has been shown that the concentrations of vitamins C and E in mice bone marrow were reduced following total body exposure to X-ray radiation.⁴ Radiation induced apoptosis in cancer radiotherapy was reduced by antioxidants, vitamins E and C, phytochemicals and micronutrients like selenium.⁵ Antioxidant phytochemicals, including flavonoids, polyphenols, carotenoids and organosulfur compounds, have been shown to have varying degrees of effectiveness as radio-protective substances.⁶,⁷

There is a need to understand the biological mechanisms of radiation-induced apoptosis. Radiation affected cells undergo apoptosis by several mechanisms. Induction of apoptosis by
ionizing radiation can occur in different cellular compartments, including the nucleus, cytosolic elements (organelles) and the plasma membrane and the generation of reactive oxygen species (ROS) is thought to be a common initiating event.

1.1 Apoptosis

The word “apoptosis” is from the ancient Greek words *apo* - from/off/without, and *ptosis* – falling. The term “apoptosis” was first introduced by John Kerr in 1972. It refers to the formation in a cell, under various initiating causes, of a morphological feature called “apoptotic bodies”. The German scientist Carl Vogt described the principle of apoptosis in 1842 and the anatomist Walther Flemming presented a more precise description of the process of programmed cell death in 1885. Sydney Brenner, H. Robert Horvitz and John E. Sulston jointly received the Nobel Prize for Medicine or Physiology in the year of 2002 for their discovery on gene regulation of organ development and programmed cell death or apoptosis in the nematode *Caenorhabditis elegans*.

Cell death by apoptosis is an active process. It plays a key role in the development of multicellular organisms. Cells that have been produced in excess during early growth and development can undergo programmed cell death to contribute to the forming of organs and tissues. Apoptosis regulates and maintains cell populations in tissues during both normal physiological and pathological conditions. In the human body around 100,000 cells are produced each second by the process of mitosis and the same number of cells die by the process of apoptosis. During the development of the brain, half of the neurons that are initially formed will die by the time the adult brain is formed.
Damage to healthy cells can also cause apoptosis. For instance, if a cell’s DNA is damaged to some extent, then it will try to repair it. If the cell is unable to repair the damaged DNA, then apoptosis may be initiated. Such a process is a protection against cancer since cells with damaged DNA can lose control of growth processes and may turn cancerous.

Scientists have shown great interest in apoptosis since a number of diseases are known to be caused or complicated by increased levels of apoptosis, including degenerative diseases such as Parkinson’s, Alzheimer’s, spinal muscular atrophy and AIDS. Decreased levels of apoptosis are known to be involved in cancer (DNA mutations in critical control proteins such as p53 and Bcl-2) or autoimmune diseases (type I diabetes or encephalomyelitis). Apoptosis can also be triggered by toxins and other cellular stresses such as oxidative stress or alcohol.11

1.2 Morphological changes of apoptosis

Apoptotic cells can be identified by a distinct set of biochemical and physical changes.15 During early stages of apoptosis, the apoptotic cell shrinks, shows membrane deformations and loses contact from the neighbouring cells. Its chromatin condenses and margins to the nuclear membrane. As the process continues, the plasma membrane shows distinct blebbing and budding. Finally, the cell is divided into compact membrane-enclosed structures called “apoptotic” bodies. These bodies have cytosol, the condensed chromatin and organelles. These are shown in the Figure 1. Macrophages engulf the apoptotic bodies and these apoptotic bodies are removed from the tissue without causing an inflammatory response.

Cells can also die via necrosis, usually after suffering a major physiological insult.18 This results in a loss of membrane integrity, swelling and breakup of the cells. The release of cellular contents into the surrounding environment can be observed during necrosis. This can damage the
surrounding cells and initiate a strong inflammatory response within the tissue.\textsuperscript{18} Figure 1 shows the generalized pathways involved in the processes of apoptosis and necrosis.

\textbf{Figure 1}: Steps involved in the process of apoptotic and necrotic cell death.\textsuperscript{15}

Cellular shrinking, chromatin condensation and margination at the nuclear periphery are observed in apoptosis, followed by the eventual formation of membrane-bound apoptotic bodies that contain organelles, cytosol and nuclear fragments which are phagocytosed without triggering inflammatory processes. During necrosis, the cell swells, becomes leaky, and finally is disrupted and releases its contents into the surrounding tissue resulting in inflammation.\textsuperscript{15,19}

1.3 Mitochondria

The word mitochondrion is derived from the Greek words \textit{mitos} (μίτος) meaning thread, and \textit{chondrion} (χονδρίον) meaning granule. Most eukaryotic cells contain mitochondria which are absent from prokaryotic cells. A mitochondrion is an organelle with inner and outer membranes.\textsuperscript{20} The size of these organelles range from 0.5 to 1.0 \textmu m in diameter. Mitochondria
are cellular power plants within the cell, converting high chemical potential molecules such as fatty acids and sugars, into more usable chemical forms such as adenosine triphosphate (ATP).\textsuperscript{21} Mitochondria are also involved in a wide range of other processes like cell signalling, cellular differentiation, cell death, as well as the control of the cell cycle and cell growth.\textsuperscript{22} It is also now becoming increasingly clear that it is in the mitochondria where the first key steps occur that lead a cell down the apoptotic cascade.\textsuperscript{23}

1.4 Mitochondria and cell death
There are three general mechanisms by which mitochondria can participate in the initiation and promotion of apoptosis, and these effects might be interrelated with each other. These mechanisms are: (i) change of cellular reduction-oxidation (redox) potential, (ii) disruption of electron transport, oxidative phosphorylation, and adenosine triphosphate (ATP) synthesis and (iii) release of proteins that trigger activation of the caspase family of proteases.\textsuperscript{1}

1.5 Reactive oxygen species (ROS)
Reactive oxygen species (ROS) are short-lived diffusible species that include hydroxyl (HO•), alkoxy (RO•) and peroxyl (ROO•) radicals. Some radicals, such as superoxide (O₂•⁻) and nitroxyl radical (NO•) species, have long lifetimes of many seconds to minutes. The non-radicals hydrogen peroxide (H₂O₂), organic hydroperoxides (ROOH) and hypochlorous acid (HOCl) are also included in ROS. ROS can damage both DNA and proteins.\textsuperscript{24} ROS may also act as chemical messengers. H₂O₂ is a secondary messenger\textsuperscript{25} that is involved in receptor-mediated signalling pathways and transcriptional activation.\textsuperscript{26} Hydrogen peroxide has been shown to induce apoptosis and this induction was prevented by catalase.\textsuperscript{27}
During the transfer of electrons to molecular oxygen during oxidative phosphorylation, an estimated 1 to 2% of electrons in the respiratory chain lose their way, most of them participating in formation of ROS.\(^2\) The production of superoxide can be increased by anything that decreases the coupling efficiency of the electron transport chain.\(^1\) Increased superoxide formation can lead to increased lipid peroxidation which is generally accepted to be an early chemical event in apoptosis.\(^2\) Manganese superoxide dismutase converts superoxide anion \(O_2^-\) into \(H_2O_2\) and \(O_2\). In the presence of transition metals such as iron (Fe\(^{3+}\)), hydrogen peroxide can be converted to hydroxyl radical via Fenton chemistry.\(^3\) This process has been shown in the Figure 2.

\[
\begin{align*}
Fe^{3+} + O_2^- & \rightarrow Fe^{2+} + O_2 \\
Fe^{2+} + H_2O_2 & \rightarrow Fe^{3+} + HO^- + HO^* \\
O_2^- + H_2O_2 & \rightarrow HO^- + HO^* + O_2
\end{align*}
\]

**Figure 2:** Redox processes in the presence of Fe\(^{3+}\).

If a sequential process is assumed, initial released ROS from mitochondria can directly or indirectly (via ceramide generation) increase the gating potential of the pore (Figure 3) on mitochondria, rendering mitochondria both as a source and target of ROS.\(^4\) The major sources of superoxide anion production in cells are mitochondria. Release of cyt c seems to be the significant event\(^1\) in apoptosis initiation, as it is a required step for aggregation of the adapter molecule Apaf1. The pro-apoptotic member of the Bcl-2 family Bax protein is responsible for
Figure 3: Role of ROS in apoptosis induction and source and target of mitochondria.\textsuperscript{24}

releasing cytochrome c from mitochondria.\textsuperscript{31} Cytochrome c exits from the mitochondrial membrane by a pore created by some Bcl–2 family members, including Bax.\textsuperscript{1} The disruption of the mitochondrial potential by ROS and opening of the mitochondrial permeability pore\textsuperscript{11} leads to the release of cytochrome c.\textsuperscript{32}
1.6 Cytochrome c (cyt c)

Cytochrome c is a small heme protein having 12 kDa molecular weight. It can be found in the inner membrane of the mitochondrion and is loosely associated with it. It is a highly soluble protein, about 100 g/L at pH 7.0. The cyt c contains 104 amino acids and a heme group that is covalently bonded to the protein. The cyt c is a chief component of the electron transport chain. It can undergo one-electron oxidation and reduction, but it does not bind to oxygen. It transfers electrons between Complexes III (Coenzyme Q - Cyt C reductase) and IV (Cyt C oxidase). The structure of human cytochrome c protein is shown in Figure 4. The orange colored iron atom is coordinated with six ligands, the nitrogen atoms from the porphyrin ring contribute four ligands, and the sulphur atom of methionine-80 and nitrogen atom of histidine-18 residues form the fifth and sixth ligands.

Figure 4: Human Cytochrome c protein.
1.7 Cardiolipin (CL)

Cardiolipin (IUPAC name: 1,3-bis(sn-3’-phosphatidyl)-sn-glycerol), is an important component of the mitochondrial inner membrane, where it comprises about 20% of the total lipid composition. CL was first isolated from beef heart in the early 1940s. Both in mammalian and plant cells, CL is found in the inner mitochondrial membrane. It is an essential component for the optimal function of many enzymes which are involved in mitochondrial energy metabolism. The generalized structure of cardiolipin is shown in Figure 5.

![Figure 5: Structure of cardiolipin, where R₁, R₂, R₃ and R₄ are 18-carbon chain fatty acid.](image)

CL is a diphosphatidylglycerol lipid, in which there are three glycerol moieties; two phosphatidylglycerols connect with a glycerol backbone to form a dimer. It thus contains four acyl groups and two negative charges. Most CL in animal tissues contains 18-carbon fatty acyl chains with two unsaturated bonds, called linoleic acid. The occurrence of these unsaturated fatty acids in mitochondria renders it the primary target of attack by free radicals.

CL is found primarily in membranes that also has the F₀F₁-ATPase. CL is the only eukaryotic phospholipid which is synthesized in mitochondria, where it remains until the cell dies. All other phospholipids are synthesized in the endoplasmic reticulum. CL has high binding affinity for the membrane proteins that are involved in the synthesis of ATP in the mitochondrion.
CL is in the inner membrane of mitochondria and is found in only small amounts in the rest of the cell. CL exists in contact with sites between the outer and inner membranes. The tBid protein targets this CL and leads to an increase in negative intrinsic curvature of the membrane, destabilizing the bilayer and likely facilitating cyt c leakage. This step is followed by the binding of CL to Bax/BaK, eliciting oligomerization and cristae remodeling that starts the destruction of the organelle.

CL can interact with the electron transport chain complexes that are involved in oxidative phosphorylation. It is important for optimal activity of the respiratory chain complexes. CL peroxidation is an early event in the release of cytochrome c and caspase activation. CL can play an important role for the integrity and function of the mitochondrial inner membrane and also associated with members of the apoptotic machinery including cytochrome c, Bid and caspase 8.
1.8 Aim & objectives

Cardiolipin (CL) peroxidation is the chief event leading to formation and release of pro-apoptotic bodies. The catalyst for the peroxidation of the CL is cytochrome c (cyt c). In normally functioning mitochondria, CL and cyt c are well separated, but in the initial stage of apoptosis, CL and cyt c form a cyt c/CL complex whose redox potential is -400 mV more negative than that of intact cyt c. The cyt c/CL complex is formed by the trans-membrane redistribution of CL allowing a physical interaction of CL and cyt c. The entire process is driven by few mitochondrial proteins. The cyt c can have two important interactions with phospholipids, one is an electrostatic interaction and other one is a hydrophobic interaction. These two kinds of interactions are necessary for cyt c to exhibit peroxidase activity. The initiation of apoptosis in irradiated cells is marked by a specific increase in the peroxidation of CL. As cyt c/CL complex formation initiates the apoptotic events, we are interested in targeting the same complex to stop the activity of the cyt c peroxidase and thus radiation-induced apoptosis. The cyt c has a heme-iron that is the catalytic site for peroxidase activity. Upon interacting with CL, cyt c partially unfolds and the heme-iron loses a methionine ligand. Unfolding of the protein opens a crevice, allowing small molecules such as H$_2$O$_2$ access to the heme iron atom. We postulated that locking the heme-iron with specific ligands would stop the peroxidase activity of cyt c/CL complex and lead to the inhibition of radiation-induced apoptosis. By considering the electrostatic and hydrophobic interactions in the cyt c, our group designed imidazole-substituted fatty acids, where imidazole might act as the sixth ligand to the heme iron.

During our initial studies we designed and synthesized (S,Z)-12-((1H-imidazol-1-yl)octadec-9-enoic acid (IOA), 12-((1H-imidazol-1-yl)octadecanoic acid (ISA), (S,Z)-methyl 12-((1H-imidazol-1-yl)octadec-9-enoate (IEOA) and 12-((1H-imidazol-1-yl)dodecanoic acid (IDA) (Figure 6).
These compounds were tested and shown to be able to inhibit cyt c peroxidase activity \textit{in vitro} and to a lesser extent in isolated mitochondria. The compound IDA did not show any inhibitor activity against cyt c peroxidase activity \textit{in vitro} and isolated mitochondria. Furthermore, IOA, ISA and IEOA could also stop the apoptotic process in cultured cells.

\textbf{Figure 6:} Structures of IOA, ISA, IEOA and IDA.\textsuperscript{46}

We designed and synthesized the TPP-12-IOA and TPP-12-ISA (Figure 7) to target the mitochondria, because of the delocalized cationic nature of triphenylphosphonium group effectively electrophoresed into the negatively charged mitochondrial membrane. TPP-12-IOA and TPP-12-ISA were tested \textit{in vitro} and \textit{in vivo}, and worked both as inhibitors of cyt c peroxidase and radiation induced apoptosis.
Later, we were interested in studying the structure-activity relationship of molecules that have the imidazole moiety at different positions (6, 8, 10, 13 and 14) along the alkyl chain (Figure 8) on inhibiting the peroxidation activity of cytochrome c.

We designed and synthesized another group of molecules that are carnitine ester derivatives (Figure 9). Carnitine esters of fatty acids are part of the controlled mechanism of import of acyl chains into the mitochondria. We hypothesized that the attachment of carnitine esters may benefit the bio-compatibility and bio-availability of these compounds compared to the previously designed TPP derivatives. These molecules were tested for the ability to inhibit cyt c peroxidase activity in vitro.
We designed and synthesized another set of compounds \textit{CDE-12-IOA} and \textit{CDE-12-ISA} (Figure 10). The double carnitine esters \textit{CDE-12-IOA} and \textit{CDE-12-ISA} are more hydrophobic and possess less detergent like properties than the single carnitine esters \textit{CSE-12-IOA} and \textit{CSE-12-ISA}. 

**Figure 10:** Structures of carnitine double esters \textit{CDE-12-IOA} and \textit{CDE-12-ISA}.
2. Results and Discussion

2.1 Synthesis of positional isomers of imidazole substituted C18 fatty acids esters

Our main goal was the synthesis of different fatty acid derivatives containing an imidazole group on the alkyl chain and esterified to a triphenylphosphonium salt to direct the compound to mitochondria. Our previous group members synthesized imidazole-substituted fatty acids and their esters. Those were imidazole substituted oleic acid (IOA), stearic acid (ISA), imidazole substituted methyl ester of oleic acid (IEOA) and imidazole substituted dodecanoic acid (IDA) (Figure 6). They hypothesized that these compounds interact with cytochrome c to position the imidazole group as a sixth ligand to the heme.46

Molecular modelling and docking studies to partially unfolded cyt c showed that imidazole group of IOA, ISA and IEOA close to heme. The distances between heme-iron and imidazole nitrogen were 2.4 Å (IOA), 2.5 Å (IEOA) and 2.7 Å (ISA). The imidazole group of compound IDA was 6.9 Å away from the heme-iron atom.46 From the above data, it was confirmed that fatty acids with chains longer than C12 can lie in a hydrophobic groove of partially unfolded cyt c. The distance between the imidazole group and heme iron plays a major role in the activity.

The Amplex Red reagent (10-acetyl-3,7-dihydroxyphenoxazine) is used to detect hydrogen peroxide (H$_2$O$_2$) (and thus indirectly peroxidase activity) in picomolar concentration. The Amplex Red reagent, in combination with horseradish peroxidase (HRP) is used to detect H$_2$O$_2$ released from biological samples, including cells, or generated in enzyme-coupled reactions. In the presence of HRP, the Amplex Red reagent reacts with H$_2$O$_2$ in a 1:1 stoichiometry to produce the red-fluorescent oxidation product, resorufin (Figure 11). Resorufin has absorption and
fluorescence emission maxima of approximately 571 nm and 585 nm, respectively. The assay for resorufin can be performed either fluorometrically or spectrophotometrically.

![Reaction of Amplex Red to H2O2](image)

**Figure 11:** Oxidation of Amplex Red to resorufin.

**Figure 12** shows the results of fluorescence Amplex Red based assay for the inhibitory activity of imidazole fatty acids and one ester against cyt c peroxidase. Here -TOCL is cyt c and H2O2 lacking 1,1′,2,2′-tetraoleoyl cardiolipin (white bar) and + TOCL is cyt c and H2O2 plus 1,1′,2,2′-tetraoleoyl cardiolipin (black bar). The compounds IEOA, IOA, ISA and IDA were tested against

**Figure 12:** Inhibition of peroxidase activity of cyt c/TOCL complexes with IEOA, IOA, ISA, and IDA.
the peroxidase activity at different concentrations (0.5 to 5 µM). The inhibitory action on peroxidase activity increased upon increasing the concentrations of IEOA, IOA and, ISA compounds. On the contrary, the compound IDA was tested at 5 µM, but did not show any inhibition of the peroxidase activity of cyt c/cardiolipin complex.

Curiously, despite the anticipated requirement of the free carboxylate for binding to cyt c, the methyl ester also showed inhibitory activity. The 12-imidazole-dodecanoate analogue was not active, illustrating that the full C₁₈ carbon chain of the fatty acid is necessary for inhibitory activity. The binding mode of the 12-IOA and 12-ISA to partially unfolded human cyt c was modeled by Drs. Judith Klein-Seetharaman and Naveena Yanamala, (Dept. of Structural Biology, University of Pittsburgh) and are shown in Figure 13.

![Figure 13: Docked modeling for the binding of IOA to cytochrome c](image)

Modelling was performed by Drs. Judith Klein-Seetharaman and Naveena Yanamala, Dept. of Structural Biology, University of Pittsburgh.
Free imidazole substituted fatty acids and esters inhibit the apoptosis in cells and targeted into mitochondria. The internal charge of mitochondria is negative and the inner membrane potential is 150-180 mV.\textsuperscript{50} The large inner membrane potential should be used for delivering the molecules to mitochondria. Generally, the presence of the cationic charge on the delivering molecule favours the interaction with mitochondria. That is why lipophilic cations can pass easily through lipid bilayers. Here our group designed and synthesized imidazole fatty esters having the triphenylphosphonium group. The triphenylphosphonium group increases the cationic surface which can assist in interacting with mitochondrial membrane. These molecules enter into the cytoplasm from the extracellular environment driven by the plasma membrane potential (30-60 mV) and again accumulated into mitochondria.\textsuperscript{50,51} Most of TPP derivatives accumulated in mitochondria\textsuperscript{46} and inhibited apoptosis in cells, similarly to IOA and ISA. Due to this reason, our group synthesized the TPP-12-IOA and TPP-12-ISA compounds.

We synthesized different positional isomers of the imidazole ring on the long carbon chain, at positions 6, 8, 10, 13 and 14. Also prepared were C\textsubscript{12} (saturated and unsaturated) imidazole carnitine monoesters as well as double esters. Compounds were sent to the Centre for Medical Countermeasures against Radiation (CMCR) at the University of Pittsburgh for biological testing. In order to prepare these compounds we started with different hydroxy fatty acids, some of which are commercially available from natural sources and some which had to be prepared synthetically. Syntheses of all these compounds are shown in the corresponding schemes.
2.2.1 Synthesis of (S, Z)-(3-((12-(1H-imidazol-1-yl)octadec-9-enoyl)oxy)propyl)triphenylphosphonium bromide (TPP-12-IOA).

TPP-12-IOA and TPP-12-ISA were synthesised from the commercially available starting material methyl ricinoleate. Both compounds were synthesized in similar manner (Scheme 1). Methyl ricinoleate 1 was mesylated by treating with methanesulfonyl chloride, in the presence of TEA and DMAP in DCM. The crude mesylated compound was heated with imidazole at 70°C to give the imidazole substituted compound 2 in 34% yield over the two steps.

\[ \text{TPP-12-IOA} \]

**Reaction Conditions:** (i) CH\textsubscript{3}SO\textsubscript{2}Cl, TEA, DMAP, DCM, 0°C to RT; (ii) imidazole, 70°C, 16h, 34%; (iii) MeOH : H\textsubscript{2}O (3:1), NaOH, RT, 89%; (iv) Compound 5, DCC, DCM, 85%; (v) TPP, toluene, 110°C, 16h, 95%.

**Scheme 1:** Synthesis of TPP-12-IOA.

We observed that most of the compound was the product of elimination because the secondary mesyl group is likely prone to this reaction. We used higher temperatures in the presence of
imidazole, and the pKa values of imidazole are 7 and 14.2\textsuperscript{53}. Hydrolysis of the imidazole methyl ester 2 with NaOH in a mixture of methanol and water gave acid 3 in 89% yield.\textsuperscript{54} Compound 4 was refluxed with TPP in toluene to produce the compound 5 in 95% yield.\textsuperscript{55,56} Compound 3 was esterified with (3-hydroxypropyl) triphenylphosphonium bromide 5 in the presence of DCC to give compound TPP-12-IOA in 85% yield.\textsuperscript{57}

2.2.2 Synthesis of (3-((12-(1H-imidazol-1-yl)octadecanoyloxy)propyl)triphenylphosphonium bromide (TPP-12-ISA)

\begin{center}
\textbf{Scheme 2: Synthesis of TPP-12-ISA.}
\end{center}

Synthesis of TPP-12-ISA was started with 12-hydroxy stearic acid methyl ester and was prepared in an analogous fashion to TPP-12-IOA. The strategy for the synthesis of compound TPP-12-ISA was shown in the above Scheme 2.
2.2.3 Biological results of TPP-12-IOA and TPP-12-ISA

TPP-12-IOA and TPP-12-ISA were both tested in *in vitro* and *in vivo* as inhibitors of cyt c peroxidase and as inhibitors of radiation induced apoptosis. Figure 14 shows the survival of mice that had been given doses of the compounds either before or directly after receiving a dose of radiation that is lethal to most of the animals by day 12 post-irradiation. For this experiment they used the three sets of mice that were observed over 60 days.

**Figure 14:** Radiation protection and mitigation by TPP-12-IOA and TPP-12-ISA.\(^{48}\)

C57BL/6NTac female mice were exposed to total body irradiation to a dose of 9.25 Gy using (a) a cesium source (\(n = 31–35\) mice per group) (b) a linear accelerator (\(n = 10–23\) mice per group). The mice were irradiated and injected intraperitoneally (i.p.) with TPP-12-IOA or TPP-12-ISA (5 mg per kg body weight in 100 \(\mu l\) of water containing 25% ethanol) 10 min after irradiation. (i) The first set mice were exposed to total body irradiation at the dose of 9.25 Gy only (black circles). (ii) The second set mice were exposed to total body irradiation at the dose of 9.25 Gy and injected with TPP-12-ISA (5 mg per kg body weight) 10 min (blue triangles) (iii) The third set of mice were exposed to total body irradiation at the dose of 9.25 Gy and injected with TPP-12-IOA (5 mg per kg body weight) 10 min (red squares).
Survival of the mice was monitored for 55 days. Most of the untreated mice (~75%) were dead after 15 days (black circles), and ~15% of mice survived from 25 to 55 days. Mice that were treated with TPP-12-IOA after radiation, showed 90% survival up to 15 days, and after that suddenly dropped to 70%, then after 25 days about 65% survived. In a third set of animals, ~90% of the mice that were treated with TPP-12-ISA were still alive at 10 days, 85% at 15 days and 55% from day 25 onward. In the same way they tested again three more sets of mice with different conditions and their results are shown in the Figure 14b.

The conditions are the same as in (a) but mice were injected with the compounds before and after irradiation. The mice were injected i.p. with TPP-12-IOA (5 mg per kg body weight in 100 μl of water containing 25% ethanol) at 1 h or 10 min before irradiation or 10 min, 5 or 24 h after irradiation. Mice were exposed to total body irradiation at the dose of 9.25 Gy only (black circles); to total body irradiation at the dose of 9.25 Gy and injected with TPP-12-IOA (5 mg per kg body weight) 10 min (blue circles), 5 h (blue triangles) and 24 h (blue squares) thereafter. Mice injected with TPP-12-IOA (5 mg per kg body weight) 10 min (red squares) and 1 h (red triangles) before total body irradiation (9.25 Gy).

In the Figure 12 (b), those animals that received injections of TPP-12-IOA ten minutes after irradiation (blue circles) showed remarkable survival rates; 100% up to 40 days, then 95% up to 55 days.
2.3.1 Synthesis of \((3-((6-(1H-imidazol-1-yl)octadecanoyl)oxy)propyl)triphenylphosphonium bromide\) (TPP-6-ISA)

TPP-12-IOA and TPP-12-ISA were tested \textit{in vitro} and \textit{in vivo} and were shown to be active as inhibitors of cyt c peroxidase. It was not obvious from the preliminary assay and modeling results whether imidazole substitution at other places on the chain would decrease or increase inhibitory activity. We therefore planned to synthesize different positional isomers of imidazole on the alkyl chain, to study the structure activity relationship of TPP-imidazole fatty acids in an attempt to identify more potent compounds. TPP-12-ISA and TPP-12-IOA were made by using commercially available 12-hydroxy steric acid and ricinoleic acid. The 6, 8, 10, 13 and 14-hydroxy fatty acids were synthesized by using different starting materials because these compounds are not commercially available. 6 and 8-Hydroxy fatty acids were synthesized from cycloalkenes. The 10-hydroxy fatty acid can also be prepared by using this method, but cyclodecene is more expensive. Because of this reason, 10-hydroxy fatty acid was prepared from 1, 10-decanediol. The 13 and 14 hydroxy fatty acids were also synthesized from 1, 12-dodecanediol.

In general, ozonolysis of olefins gives the dialdehydes but conditions exist that produce a methyl ester and an aldehyde. Starting from a cyclic alkene would therefore provide a differentially terminally functionalized linear alkyl chain. Cleavage of cyclohexene 9 by passing ozone gas at -78°C through a suspension of compound 9 and NaHCO\(_3\) in DCM, followed by the addition of Ac\(_2\)O and TEA for 15 minutes produced the aldehyde 10 in 63% yield.\(^{58, 59}\) Compound 10 in THF was added to dodecylmagnesium bromide at -20°C, which was prepared from 1-bromododecane and magnesium metal in THF, to give the alcohol 11 in 47% yield. This
alcohol 11 was converted into the mesylate, and the mesyl group was displaced with imidazole to provide compound 12 in 34% yield.

**Reaction Conditions:**
(i) NaHCO₃, ozone gas, -78°C, DCM, TEA, Ac₂O, DCM, 16h, 63%;
(ii) 1-bromododecane, Mg, THF, -20°C, 3h, 47%;
(iii) CH₃SO₂Cl, TEA, DMAP, DCM, 0°C to RT, Imidazole, 70°C, 16h, 34%;
(iv) MeOH : H₂O (3:1), NaOH, RT, 3h, 77%;
(v) Compound 5, DCC, DCM, 16h, 67%.

**Scheme 3:** Synthesis of TPP-6-ISA.

Hydrolysis of compound 12 in the presence of a base gives carboxylic acid 13 in 77% yield. The carboxylic acid 13 was coupled with phosphonium salt 5 to produce TPP-6-ISA in 67% yield. The last three steps were the same as those for the previous compounds TPP-12-IOA and TPP-12-ISA (Scheme 1).
2.3.2 Synthesis of (3-((8-(1H-imidazol-1-yl)octadecanoyloxy)propyl)triphenylphosphonium bromide (TPP-8-ISA)

Reaction Conditions: (i) a) Cyclohexene, NaHCO$_3$, ozone gas, -78°C, DCM, TFA, Ac$_2$O, DCM, 16h, 70%; (ii) 1-bromododecane, Mg, THF, -20°C, 2h, 47%; (iii) CH$_3$SO$_2$Cl, TEA, DMAP, DCM, 0°C to RT, Imidazole, 70°C, 16h, 35%; (iv) MeOH : H$_2$O (3:1), NaOH, RT, 83%; (v) Compound 5, DCC, DCM, 70%.

Scheme 4: Synthesis of TPP-8-ISA.

Compound TPP-8-ISA was synthesized by using the procedures of compound TPP-6-ISA but yields were little bit different from previous compound TPP-6-ISA. All the yields and conditions are shown in Scheme 4.
2.3.3 Biological results of compounds TPP-6-ISA and TPP-8-ISA

Compounds **TPP-6-ISA** and **TPP-8-ISA** were tested and found to be competent inhibitors of cyt c peroxidase in *in vitro*. Based on these results we decided to study the structure activity relationship of different positional isomers of TPP-imidazole fatty acids to potentially identify more potent compounds. The aim is to create a robust structure-function study of these compounds to guide the choice of the best compound for further studies in mice. Compounds with the imidazole group substituted at C-6 or C-8 were synthesized and sent to our collaborators at the Centre for Medical Countermeasures against Radiation (CMCR) at the University of Pittsburgh.

![Figure 15:](image)

**Figure 15:** TPP-imidazole-stearic acid derivatives (TPP-ISAs) inhibit peroxidase activity of cyt c/TOCL complexes. New derivatives: TPP-6-ISA and TPP-8-ISA, and TPP-12-ISA.

**Conditions:** buffer 20 mM HEPES (pH 7.4) with 100 µM DTPA, 1 µM cyt c 50, µM Amplex Red, 50 µM H₂O₂.
In Figure 15 blue and red colored bars indicate fluorescence intensity of cyt c and cyt c + TOCL respectively. The cyt c/TOCL complex showed the maximum peroxidase activity. The inhibitory studies were performed on 6-, 8- and 12-imidazole TPP stearates at various concentrations. At lower and higher concentration (0.5 µM and 5 µM) for all three compounds, inhibitory action against peroxidase activity was found to be very similar. But at moderate concentration (1 µM and 2.5 µM) TPP-6-ISA and TPP-8-ISA appeared to be significantly better inhibitors compared to the TPP-12-ISA.

2.4 Synthesis of (3-((10-(1H-imidazol-1-yl)octadecanoyl)oxy)propyl)triphenylphosphonium bromide (TPP-10-ISA)

The preparation of compound TPP-10-ISA is shown in Scheme 5. The 10-hydroxy fatty acid starting material is not commercially available. TPP-10-ISA can be synthesized by the ozonolysis of cyclodecene. But this starting material is very expensive. Due to this reason, the synthesis was started with decane-1,10-diol 19 which was treated with benzyl bromide and Ag$_2$O in DCM at reflux for 16 h to give the mono protected compound 20 in 65% yield.$^{60}$ Compound 20 was oxidized with PCC in DCM$^{61}$ to produce the aldehyde 21 in 78% yield. The bromooctane was first converted to a Grignard reagent with Mg metal and iodine in dry THF, and the solution so prepared was added to the aldehyde 21 in THF solution at 0°C to give the compound 22 in 61% yield. Mesylation of hydroxyl compound 22 was achieved with methanesulfonyl chloride, TEA and DMAP in DCM, which was substituted with imidazole by heating without solvent at 70°C for 16h to give the compound 23 in 33% yield. Compound 23 was debenzylated with 10% palladium on carbon in ethanol under hydrogen gas balloon at reflux for two days to produce
hydroxyl compound 24 in 81% yield. Compound 24 was converted into acid 25 with freshly prepared Jones reagent in acetone water mixture for 3 hours in 84% yield. The acid 25 was esterified with compound 5 by using DCC, DMAP in DCM to produce TPP-10-ISA in 77% yield.

**Reaction Conditions:** (i) BnBr, Ag₂O, DCM, reflux, 18h, 65%; (ii) PCC, DCM, 4h, 78%; (iii) Bromooctane, Mg, dry THF, 4h, 61%; (iv) a) CH₂SO₂Cl, TEA, DMAP, DCM, 2h; b)Imidazole, 16h, 70°C, 32.5%; (v) 10% Pd-C, EtOH, reflux, 2 days, 81%; (vi) Jones reagent, Acetone, 3h, 84%; (vii) compound 5, DCC, DCM, 16h, 77%.

**Scheme 5:** Synthesis of TPP-10-ISA
2.4.1 Synthesis of (3-((13-(1H-imidazol-1-yl)octadecanoyloxy)propyl)triphenyl-phosphonium bromide (TPP-13-ISA)

**Reaction Conditions:** (i) 48% HBr in H₂O, Toluene and reflux, 3h, 78%; (ii) PCC, DCM, 4h, 72%; (iii) 1-bromopentane, Mg, THF, 2h, 58%; (iv) NaCN, DMF, 16h, 92%; (v) CH₃SO₂Cl, TEA, DMAP, DCM, 0°C to RT, 2h, Imidazole, 70°C, 16h, 33%; (vi) NaOH, EtOH, H₂O, reflux, 81%; (vii) Compound 5, DCC, DCM, 78%;

**Scheme 6: Synthesis of TPP-13-ISA**

Compound **TPP-13-ISA** (Scheme 6) was prepared from 1,12-dodecanediol 26 by mono bromination with 45% HBr in water and toluene at reflux for 3 hours to give compound 27 in
78% yield. Oxidation of alcohol 27 with PCC in DCM for 4h produced the aldehyde 28 in 72% yield. Pentyl magnesium bromide was prepared from bromopentane using magnesium metal in THF, which was added to compound 28 to give the alcohol 29 in 58% yield. The extension of one carbon on bromoalcohol 29 was achieved by the reaction between compound 29 and NaCN in DMF at 90°C to give compound 30 in 92% yield. Compound 30 was mesylated followed by imidazole substitution to give the compound 31 in 32% yield. Hydrolysis of compound 31 with NaOH in ethanol at reflux for 16h gave the acid 32 in 81% yield. Finally, the acid 32 was esterified with compound 5 using DCC and DMAP in DCM to produce the final compound TPP-13-ISA in 78% yield as a gummy liquid.

2.4.2 Synthesis of (3-((14-(1H-imidazol-1-yl)octadecanoyl)oxy)propyl)triphenyl-phosphonium bromide (TPP-14-ISA)

Synthesis of TPP-14-ISA (Scheme 7) was started with compound 27 which was prepared in previous Scheme 6. Our goal was to extend the fatty acid chain by two carbon atoms on. It is possible by the substitution of bromo compound 27 with diethyl malonate. So the bromo compound 27 was treated with diethyl malonate in the presence of base and KI at reflux conditions to produce the compound 33 with extension of two carbon atoms in 63% yield. Compound 33 was treated with PCC to produce the aldehyde 34 in 73% yield. The produced aldehyde 34 was treated with Grignard reagent to give the secondary alcohol 35 in 63% yield. Compound 35 was mesylated and substituted with imidazole at 70°C to produce the compound 36 in 33% yield.
Reaction Conditions: (i) Diethyl malonate, K₂CO₃, KI, Acetonitrile, 90°C, 16h, 63%; (ii) PCC, DCM, 3h, 73%; (iii) 1-bromobutane, Mg, dry THF, 2h, 63%; (iv) CH₃SO₂Cl, TEA, DMAP, DCM, 0°C to RT.; imidazole, 70°C, 16h, 33%; (iii) MeOH : H₂O (3:1), NaOH, RT, 170°C, 15min, 68%; (iv) Compound 5, DCC, DCM, 71%.

Scheme 7: Synthesis of TPP-14-ISA

Hydrolysis followed by mono decarboxylation of diester 36 produced the mono acid 37 in 68% yield. The mono acid 37 was esterified with compound 5 and DCC to obtain compound TPP-14-ISA in 71% yield.
2.4.3 Biological results of compounds TPP-6-ISA, TPP-8-ISA, TPP-10-ISA, TPP-12-ISA, TPP-13-ISA and TPP-14-ISA

**Figure 16**: Effect of TPP-imidazole-stearic acid (TPP-ISA) derivatives on peroxidase activity of cyt c/TOCL complexes assessed by H$_2$O$_2$-dependent oxidation of Amplex Red.

**Conditions**: cyt c (1 μM), H$_2$O$_2$ (50 μM), Amplex Red (50 μM). Experiments were performed in 20 mM HEPES buffer (pH 7.4) containing DTPA (100 μM), cyt c was incubated with DOPC/TOCL liposomes (1:1) at ratio TOCL/cyt c 25:1.

**Insert**: Effect of TPP-10-ISA on peroxidase activity of cyt c/TOCL complexes.

In **Figure 16** the grey and black colored bars represent fluorescence intensity of cyt c and cyt c/TOCL complex respectively. TPP imidazole stearic acids conjugates (6, 8, 10, 12, 13 and 14) were tested against the peroxidase activity *in vitro* by using Amplex Red as quantitative fluorescent indicator. The conjugates showed similar activity at higher concentrations (2.5 μM and 5 μM), but at lower concentrations (0.5 μM and 1 μM), TPP-6-ISA and TPP-8-ISA showed higher inhibitory action compared to other derivatives. The compound TPP-14-ISA at different
concentrations (0.5 μM to 5 μM) showed the lowest inhibition against peroxidase activity compared to other conjugates.

2.5.1 Synthesis of Carnitine esters of IFAs

Within the cell, import of fatty acids into mitochondria is strictly controlled. Free fatty acids are in very low concentration in most cells, occurring rather as esters with co-enzyme A or bound to binding and transfer proteins.  

Mainly three proteins are involved in this transport system carnitine palmitoyltransferase I (CPT-I), carnitine acylcarnitine translocase (CACT) and carnitine palmitoyltransferase II (CPT-II). Each one of these proteins is located in different regions of mitochondria. Acyl-CoAs are synthesized by the catalytic action of long chain acyl-CoA synthetase (LCAS) in the mitochondrial outer membrane (MOM), then are transformed to acylcarnitines. CPT-I catalyzed this transesterification in the MOM. The formed long-chain acylcarnitines are transferred into the mitochondrial matrix by an exchange reaction catalyzed by CACT, an integral inner membrane protein. The acylcarnitines are then exchanged to the corresponding acyl-CoAs within the matrix by CPT-II, an enzyme associated with the inner leaflet of the mitochondrial inner membrane (MIM).  

We synthesized carnitine esters of IFAs as these may also allow selective drug import into mitochondria by a more specific means than did the TPP conjugates.

2.5.2 Synthesis of mono(2-(((S,Z)-12-(1H-imidazol-1-yl)octadec-9-enoyl)oxy)-3-carboxy-\textit{N},\textit{N},\textit{N}-trimethylpropan-1-aminium) mono(2,2,2-trifluoroacetate) monochloride (CSE-12-
IOA) and mono(2-((12-(1H-imidazol-1-yl)octadecanoyl)oxy)-3-carboxy-N,N,N-
trimethylpropan-1-aminium) mono(2,2,2-trifluoroacetate) monochloride (CSE-12-ISA)

Reaction Conditions: (i) Oxalyl chloride, DMF, DCM, (ii) Carnitine, TFA, 45°C, 75%

Scheme 8: Synthesis of CSE-12-IOA and CSE-12-ISA
Both carnitine esters CSE-12-IOA and CSE-12-ISA were prepared and purified by the same process. First, imidazole fatty acids 3 and 9 were converted into acid chlorides 38 and 40 with oxalyl chloride in DCM separately, and then these prepared acid chlorides were added to carnitine hydrochloride in TFA and heated at 50°C to produce the carnitine esters CSE-12-IFA and CSE-12-ISA in 75% yield.68,69 CSE-12-IFA and CSE-12-ISA were purified by precipitation method. These pure compounds were obtained as TFA salts. We tried to convert TFA salts into HCl salts by using 6N HCl in dioxane. These TFA salts were dissolved in 1,4-dioxane, then 6N HCl was added to it and concentrated under reduced pressure. This process was repeated for 3 times to get CSE-12-IFA and CSE-12-ISA as HCl salts. But, CSE-12-IFA and CSE-12-ISA were obtained as the 1:1 ratio of TFA and HCl salts.

2.5.3 Biological results of CSE-12-IOA (12-CIOFA) and CSE-12-ISA (12-CISFA).

![Graph](image)

**Figure 17:** Cytotoxicity of TPP or carnitine conjugated fatty acid in mouse embryonic cells.

Cells were seeded in 24-well plate at a density of 0.02×10⁶/well and allowed to attach overnight. Cells were then incubated with fatty acid conjugates at the indicated concentration (1.25, 2.5, 5,
10 and 20 μM) for 48 hours. The cytotoxicity of fatty acid conjugates were assessed by annexin V/propidium iodide assay (flow cytometry) or Alarma blue assay (fluorescent spectrophotometry). (Data provide by the CMCR)

**Figure 17** shows that 12-CIOFA and 12-CISFA had very minimal detrimental effect at different concentrations on cell growth on non-treated cells, compared to 6- and 8-imidazole TPP derivatives which were shown to have concentration dependent growth inhibition of cells beyond a few micromolar concentration.

![Graph showing annexin V positive cells vs concentration](image)

**Figure 18: Radiomitigative effect of TPP or carnitine conjugated fatty acid in mouse embryonic cells.** Cells were seeded in 6-well plate at a density of 0.05×10^6/well and allowed to attach overnight. Fatty acid conjugates were added to cells 15 min after gamma-irradiation exposure (10 Gy). Irradiation induced cell death was assessed by Annexin V/Propidium iodide staining assay using flow cytometry after 48 hours incubation. Data presented are the Annexin V positive cells. (Data provide by CMCR)
**Figure 18** shows that 12-CIOFA and 12-CISFA did not exhibit radiomitigative effects at concentrations ranging from 1 - 5 μM, whereas the 6- and 8-imidazole TPP derivatives showed a concentration dependent (1 μM to 5 μM) increase in radiomitigative effects, as assessed by a decreasing degree of annexin V positive cells, a marker for apoptosis.

![Graph showing annexin V positive cells vs carnitine conjugated imidazole fatty acid concentration](image)

**Figure 19** shows that the cytotoxic effects of 12-CIOFA and 12-CISFA are concentration dependent beginning at ~100 μM. At 400 μM is the compounds are highly toxic to the cells. Compounds 12-CIOFA and 12-CISFA has also shown to reduce the cell growth at increasing concentrations.

**Figure 19**: Cytotoxicity of carnitine conjugated imidazole fatty acids (CISFA and CIOFA) in mouse embryonic cells. Cells were seeded in 24-well plate at a density of 0.015×10^6/well and allowed to attach overnight. Cells were then incubated with fatty acid conjugates at the indicated concentration (50, 100, 200 and 400 μM) for 48 hours. The cytotoxicity of fatty acid conjugates were assessed by annexin V/propidium iodide assay (flow cytometry) or Alarma blue assay (fluorescent spectrophotometry). (Data provided by CMCR)
Figure 20: Radiomitigative effects of carnitine conjugated imidazole fatty acids in mouse embryonic cells. Cells were seeded in 6-well plate at a density of 0.05×10^6/well and allowed to attach overnight. Fatty acid conjugates (final, 50, 100, 200 and 400 μM) were added to cells 15 min after gamma-irradiation exposure (10 Gy). Irradiation induced cell death was assessed by Annexin V/Propidium iodide staining assay using flow cytometry after 48 hours incubation. Data presented are the Annexin V positive cells.

Figure 20 shows that the carnitine esters 12-CIOFA and 12-CISFA have mild radiomitigative effects up to 100 μM concentration. At concentrations of 12-CIOFA and 12-CISFA higher than 100 μM, cytotoxic properties were shown to dominate.

We inferred that the problem can be caused by either the detergent like properties of the compounds or cleavage of carnitine ester before inhibition. Detrimental effects of free fatty acids on mitochondria result in elevated levels of ROS via uncoupling of oxidative phosphorylation which further reduces the intracellular levels of glutathione by deterioration of endogenous antioxidant defence mechanism. Incorporation of another methyl ester group on carnitine such as, methyl carnitine ester might render hydrophobic and detergent like properties which can
assist in easy absorption into the cells with low cytotoxicity. We hypothesis that the nonspecific esterases may cleave the 3-caboyx ester bond thereby releasing the fatty acid carnitine ester which is later absorbed into the mitochondrion where the carnitine ester is cleaved. Synthesis of double carnitine esters, such as CDE-12-IOA and CDE-12-ISA are shown Scheme 9.

2.6 Synthesis of 2-(((S,Z)-12-(1H-imidazol-1-yl)octadec-9-enoyl)oxy)-4-methoxy-N,N,N-trimethyl-4-oxobutan-1-aminium iodide (CDE-12-IOA) and 2-((12-(1H-imidazol-1-yl)octadecanoyl)oxy)-4-methoxy-N,N,N-trimethyl-4-oxobutan-1-aminium iodide (CDE-12-ISA)

![Chemical structures of CDE-12-IOA and CDE-12-ISA]

**Reaction Conditions:** (i) Carnitine hydrochloride, 57% HI in water, methanol, reflux, 6h, 60%, (ii) compound 3 or 9, compound 41, DCC, DMAP, THF and DCM, 16h.

**Scheme 9:** Synthesis of CDE-12-IOA and CDE-12-ISA.
Carnitine methyl ester 41 was prepared by refluxing carnitine hydrochloride 39 in methanol and hydroiodic acid for 16 h.\textsuperscript{71} The carnitine methyl ester 41 was esterified with compounds 3 and 9 to give the compound \textbf{CDE-12-IOA} and \textbf{CDE-12-ISA} respectively (Scheme 9).\textsuperscript{72}
3. Conclusion and Future Work

We synthesized six positional isomers of imidazole substituted fatty acids (6, 8, 10, 12, 13, and 14 stearates, plus 12-imidazole substituted oleate) as the TPP ester derivatives. We also prepared the 12-imidazole carnitine single esters and double esters as the saturated and unsaturated fatty acid derivatives. TPP-12-IFA and TPP-12-ISA derivatives were tested in *in vitro* and *in vivo*, and showed dose dependent inhibition of cyt c peroxidase activity. The TPP imidazole fatty acid derivatives and the single carnitine esters were tested only *in vitro*. Of all these tested compounds, compound TPP-8-ISA has more inhibitory activity *in vitro* against the cyt c peroxidase activity compared to the other compounds. Single carnitine esteres showed low inhibiter activity against the peroxidase activity. We are hoping to receive biological data on the double carnitine esters in the near future. After getting those results we will confirm whether it is worth pursuing the carnitine double esters.

TPP-8-ISA was tested as a racemic mixture *in vitro* against the cyt c peroxidase activity. Both isomers of the TPP-8-ISA will be synthesized separately and will be tested against the cyt c peroxidase activity in order to affirm which isomer shows high inhibition. 8-hydroxy fatty acid will be used as a starting material to synthesize the two isomers of TPP-8-ISA. In the beginning, secondary alcohol will be oxidised to a ketone followed by converting it back to an alcohol in the presence of chiral catalyst to obtain a single isomer of an 8-hydroxy fatty acid. This single isomer (R or S) of the alcohol will then be converted into another isomer (S or R) by using Mitsunobu reaction. These two alcohols will then be transformed into two single isomers (R and S) of TPP-8-ISA.
4. Experimental

General

All reagents were purchased from Sigma – Aldrich Co., Oakville, Ontario. All glassware was dried in an oven at 90°C overnight, and then cooled in desiccators before use. Cooling baths were prepared with dry ice in ethyl acetate for -78°C and ice/salt mixture for 0°C – 15°C. All air and moisture sensitive reactions were performed under nitrogen gas. THF and Et₂O were distilled with sodium/benzophenone before use. DCM was dried over CaH₂. Methanol was distilled from Mg/iodine. Reagent grade solvents were used for extraction and column purifications. Distilled water was used for all aqueous workups.

Analytical thin layer chromatography (TLC) was done on Merck 0.25 mm pre-coated silica gel 60 Å F-254 on aluminum sheets and visualized under UV light or stained with iodine in silica gel, KMnO₄ solution, ninhydrin solution or vanilin solution. Column chromatography was performed on silica gel 230 – 400 mesh purchased from SiliCycle Inc, Quebec, Canada.

¹H NMR and ¹³C NMR spectra were measured on a Bruker Advance DPX – 300 digital FT – NMR spectrometer (300 and 75 MHz respectively) and Bruker 600 NMR spectrometer (600 and 151 MHz respectively) in CDCl₃ with residual chloroform as internal reference (7.281 ppm for ¹H and 77.0 for ¹³C) unless otherwise mentioned. Chemical shifts were reported as δ values and coupling constants (J) were reported in Hertz (Hz). The following abbreviations were used as s (singlet), d (doublet), t (triplet), q (quartet), m (multiplet) and br (broad). Mass spectra (MS) were recorded on Carlo Erba/Kratos GC/MS Concept 1S double focusing mass spectrometer interfaced to a Kratos DART acquisition system and a Sun SPARC workstation. Samples were introduced through a direct inlet system. Ions were generated by using electron impact (EI) or Fast Atom Bombardment (FAB) and were reported as m/z values.
Synthesis of (R,Z)-methyl 12-(1H-imidazol-1-yl)octadec-9-enoate (2)

Methyl ricinoleate (1) (10.0 g, 32 mmol), TEA (5.8 ml, 41.60 mmol) and DMAP (0.39 g, 3.2 mmol) were dissolved in dry DCM (150 ml), cooled to 0°C, then methanesulfonyl chloride (2.72 ml, 33.60 mmol) was added slowly under nitrogen gas, stirred at room for another 2 h. The reaction mixture was diluted with DCM, washed with water, brine solution, dried over anhydrous MgSO₄ and then concentrated. This crude compound was heated with imidazole without solvent at 70°C for 16 h under a nitrogen atmosphere. The crude product was purified by silica gel column chromatography (2% MeOH in DCM) and provided compound 2 (3.95 g, 34%) as a gummy liquid.

TLC  \( R_f = 0.45 \) (5% MeOH in DCM, KMnO₄ and iodine active.)

Synthesis of (S, Z)-12-(1H-imidazol-1-yl)octadec-9-enoic acid (3)

To a stirred solution of compound 2 (2.50 g, 6.9 mmol) in a mixture of MeOH (30 ml) and water (10 ml), was added NaOH (0.83 g, 20.67 mmol) at 0°C, which was then allowed to warm to room temperature and stirring was continued for another 3 h. The reaction mixture was concentrated to remove methanol, then the aqueous layer was acidified with 1N HCl to pH 4, and extracted with DCM (3x50 ml). The combined organic layers were washed with brine solution, dried over anhydrous MgSO₄ and then concentrated. The crude product was purified by silica gel column chromatography (5% MeOH in DCM) to obtain compound 3 (2.16 g, 89%) as a pale yellow gummy liquid.

**Synthesis of methyl 6-hydroxyoctadecanoate (11)**

![Methyl 6-hydroxyoctadecanoate](image)

Magnesium metal (0.359 g, 14.56 mmol) was added into dry THF (10 ml) in a 100 ml two-necked round bottom flask which was equipped with condenser and nitrogen gas inlet. The
flask was heated to 70°C, then four to five drops of 1, 2-dibromoethane was added to the reaction mixture, followed by slow addition of 1-bromododecane (2.92 g, 11.726 mmol) at reflux and stirring continued another 30 min. The Grignard reagent was added drop wise to a stirred solution of methyl 6-oxohexanoate (1.31 g, 11.49 mmol) in THF (15 ml) at -20°C. The reaction mixture was slowly brought to room temperature, and stirring continued for another 2h. The mixture was quenched with saturated ammonium chloride solution, extracted with (3x40ml) of ethyl acetate and the combined organic layers were washed with brine solution, dried on anhydrous MgSO₄, concentrated. The crude compound was purified by silica gel column chromatography (2:8 ethyl acetate and hexanes) to offer compound 11 as a white coloured low melting solid (1.55 g, 47%).

**TLC**  
R<sub>f</sub> = 0.42 (20% ethyl acetate in hexanes, iodine and KMnO₄ active).
